ABSTRACT

Included are embodiments for ReNAT communications address communications. Some embodiments include a network operations center (NOC) that includes a ReNAT twin NAT that translates between a customer-assigned private IP address and a unique private IP (UPIP) address. The NOC may additionally include a ReNAT VPN component coupled to the ReNAT twin NAT, where the ReNAT VPN provides a source IP address to the ReNat twin NAT. The NOC may include logic that when executed by a processor, causes the processor to facilitate communication between a user workstation on a private network and a remote computing device, wherein facilitating communication includes receiving the data from the user workstation via a traditional VPN portal, wherein address translation has been performed by a ReNAT twin NAT client on the user workstation.

RENAT SYSTEMS AND METHODS**CROSS REFERENCE**

This application is a continuation of PCT application No. PCT/US14/10023, filed Jan. 2, 2014, and entitled Systems and Methods for Providing a ReNAT Communications Environment, which claims the benefit of U.S. Provisional Application No. 61/748,248 filed Jan. 2, 2013, both of which are hereby incorporated by reference in its entirety.

BACKGROUND**1. Field**

Embodiments provided herein generally relate to providing a ReNAT communications environment, and particularly to Systems and methods for providing ReNAT functionality across a network.

2. Technical Background

The Internet supports worldwide communication between computers using a group of standard protocols. One of these protocols, the Internet Protocol (IP), assigns a unique address to each computer known as an IP address. IP is currently available in two versions: IPv4 with 32 bit addresses, and IPv6 with 128 bit addresses.

Growth of the Internet has caused utilization of all available 32 bit addresses in IPv4. One result of the limited number of addresses is that most organizations now use one of the three private address spaces defined by IPv4. These private IP addresses cannot be used on the public Internet. Gateway routers manage the interface between a private intranet and the public Internet. Gateway routers provide various functions to hide or mask the private internal IP when communication outside the private network is required.

One common method used by gateway routers in commercial environments is the creation of a virtual private network (VPN) to connect external users to the internal private network. The VPN provides an envelope or wrapper protocol to hide the internal IP addresses and data while the packet is routed across the public Internet to the user.

ReNAT architecture provides a mechanism for multiple organizations using a VPN with private address realms to share a public software resource on the Internet. Each organization uses a VPN to communicate with remote users over the public Internet. In this way, the VPN creates a virtual tunnel between the organization's private IP network and servers and the remote user. Each VPN provides two functions to enable secure communication. The first function is that information in the virtual tunnel may be encrypted to protect it from unauthorized access. The second function is that organization's private IP network is extended to the user workstation.

While the use of private IP addresses and VPN allows users to securely access private networks, these two facts mean that organizations using VPNs cannot make use of software functions on the public Internet. Other issues are additionally present and will be discussed in more detail, below.

BRIEF DESCRIPTION OF THE DRAWINGS

The embodiments set forth in the drawings are illustrative and exemplary in nature and not intended to limit the subject matter defined by the claims. The following detailed description of the illustrative embodiments can be understood when read in conjunction with the following drawings, where like structure is indicated with like reference numerals and in which:

FIG. 1 depicts a network environment for communicating data with a remote computing device, according to embodiments described herein;

FIG. 2 depicts yet another computing environment, utilizing a twin NAT configuration, according to embodiments described herein;

FIG. 3 depicts a computing environment to communicate with a remote computing device, according to embodiments described herein;

FIG. 4 depicts a computing environment for communicating with a remote computing device without utilizing a VPN, according to embodiments described herein;

FIG. 5 depicts a flowchart that includes actions that a client workstation may perform for communicating with a remote computing device, according to embodiments described herein;

FIG. 6 depicts a flowchart that includes actions that a user workstation may perform in facilitating communication with a remote computing device once a session has been established, according to embodiments described herein;

FIG. 7 depicts another flowchart that includes actions that a NOC may perform in facilitating communication between a user workstation and a remote computing device, according to embodiments described herein;

FIG. 8 depicts a yet another flowchart that includes actions that a NOC may perform in facilitating communication between a user workstation and a remote computing device, according to embodiments described herein;

FIG. 9 depicts a flowchart that includes actions that a user workstation may perform in receiving data from a remote computing device via a NOC, according to embodiments described herein; and

FIG. 10 depicts various hardware components that may be present in a NOC, according to embodiments described herein.

DETAILED DESCRIPTION

Embodiments described herein include ReNAT systems and methods for facilitating communication between a user computing device in a private realm and a remote computing device over a wide area network (or other network). Specifically, the user computing device may communicate with the remote computing device via a satellite network or other network that may have slower than desired connection speeds. While the user may utilize a virtual private network, the communication may be routed from a user workstation, which includes a ReNAT twin NAT (network address translation) client and a commercial off the shelf (COTS) VPN client to a network operations center (NOC). The NOC includes a COTS VPN, COTS clear text software, a ReNAT Twin NAT, and a ReNAT VPN.

Accordingly, embodiments described herein provide a process to allow a group of organizations with network access using VPN communication with private address realms to share software functions, such as acceleration technology. COTS acceleration technology is currently available and may operate on clear text inside an organization's private IP network. In operation, embodiments described herein create a private IP realm or address space that is isolated from both the public Internet IP addresses and the organization's private IP addresses. Accordingly, embodiments described herein assign a unique private IP address (UPIP) for each organization system that communicates through the COTS process, so that all organization systems have unique IP addresses within the ReNAT private IP realm. The ReNAT twin NAT clients translate between a customer-assigned private IP address and

3

assigned UPIP so that the COTS clear text component, which may be configured as clear text process software, has unique IP addresses for all user organization systems even when multiple organizations have the same private IP addresses.

Outside the ReNAT environment, a user application (on the user workstation) and the corporate office remote computing device see only the customer's internal private IP addresses. The ReNAT twin NAT client and the ReNAT twin NAT are coordinated to translate between customer-assigned private IP addresses and ReNAT assigned UPIP so that the user application and corporate office server see only the organization's internal private IP addresses.

Additionally, some embodiments described herein are configured for facilitating translation of network addresses for communications between a client workstation and a wide area network. In some embodiments, the translation traverses a virtual private network (VPN), as discussed above. Accordingly, these embodiments may be configured as a two-way communication, where the Dual NAT software assigns a family of IP addresses (in IPv4, IPv6, or other similar protocol) to a private realm, such as a corporate network. Similarly, on the network operations center (NOC) side (which is between the private realm and the wide area network), a plurality of IP addresses are assigned, one for each private realm. As an example, a first private realm may be assigned IP addresses 10.0.0.x, where x=1, . . . , n. The NOC may associate those addresses with an IP address, such as 10.254.254.254 and other private realms may be associated with IP addresses, such as 10.254.254.253, etc., each having 10.0.0.x as an in-network address. Additionally, the NAT relationships may be stored in the two Dual NATs, which facilitate translation from a user computing device on a private network with a server at a corporate office, while the client workstation and the wide area network are unaware of any IP address conversion.

Additionally, some embodiments provide a source IP address on external packets to identify a source gateway or second VPN. Packets from a Dual NAT may include the destination public IP address to identify the destination gateway or second VPN.

Still some embodiments described herein provide a virtual private network within a network operations center (NOC) for facilitating communication of data between a wide area network and a client workstation in a private realm. As described above, the NOC may be configured to facilitate communication of data between the private realm and the wide area network, such as through a satellite communication, using acceleration techniques. Accordingly, the VPN created in the NOC may be utilized to provide a security barrier such that commercial off the shelf (COTS) operations are only performed within a device and never communicated between devices. Embodiments described herein may additionally facilitate assignment of IP addresses in IPv4 and/or IPv6, via utilization of the dual NATs.

Referring now to the drawings, FIG. 1 depicts a network environment for communicating data with a remote computing device 126, according to embodiments described herein. As illustrated, the network environment includes a user workstation 102, which may include a personal computer, tablet, mobile computing device, etc. The user workstation 102 may be configured for communicating with the remote computing device 126 via a private IP realm 104. The user workstation 102 may include user applications 108, as well as a ReNAT twin NAT client 110 and a COTS VPN client 112 for creating a private IP realm or address space (ReNAT Private IP Realm) that is isolated from both the public Internet IP addresses and using an organization's private IP addresses. Specifically, ReNAT twin NAT client 110 assigns a unique private IP

4

address (UPIP) for each computing device accessing the private IP realm 104 (such as user workstation 102) that communicates through the COTS VPN client, so that all computing devices (such as the user workstation 102) have unique IP addresses within the private IP realm 104. ReNAT twin NAT client 110 provides paired and coordinated twin NAT functions to manage the private IP realm of the remote computing device 126.

Included within the private IP realm 104 are a COTS VPN 114, a COTS clear text functions 116, a ReNAT twin NAT 118, and a ReNAT VPN 120. The ReNAT twin NAT client 110 and the ReNAT twin NAT 118 translate data between customer assigned private IP addresses and assigned UPIP so that the COTS clear text functions 116 has unique IP addresses for all user organization systems even when multiple organizations have the same private IP addresses.

Outside the private IP realm 104, the user application 108 and remote computing device 126 in the corporate office 106 see only the customer's internal private IP addresses. The ReNAT twin NAT client 110 and ReNAT twin NAT 118 are coordinated to translate between customer assigned private IP addresses and ReNAT-as signed UPIP so that the user applications 108 and remote computing device 126 see only the user workstation 102 internal private IP addresses. As such, the data sent from the user workstation 102 is received at the corporate office 106 at a gateway device 122 on a private network 124. The remote computing device 126 may then process the data accordingly.

Also depicted in FIG. 1 are the existing software functions 128 and the ReNAT functions manager 130. These components represent existing logic that may be utilized and/or accessed by the other components referenced in FIG. 1.

FIG. 2 depicts yet another computing environment, utilizing a twin NAT configuration, according to embodiments described herein. As illustrated, the user workstation 202 may send data to an NOC 204 by translating private IP addresses into UPIP addresses. The data may then be translated back to private addresses before being sent to a corporate office 206. The user workstation 202 includes user applications 208, as well as client software 209. The client software 209 includes a ReNAT twin NAT client 210, a COTS clear text process (CTP) COTS CTP client 212, a COTS VPN client 214, a client login manager 216, and a client session manager 218. Specifically, the user applications 208 may instruct the user workstation 202 to send data to the remote computing device 234 on the corporate office 206. As such, the client login manager 216 may facilitate the communication of login credentials for the NOC 204. Upon logging the user into the NOC, the client session manager 218 may provide user interfaces and/or other data for identifying and/or accessing the desired computing device (in this case the remote computing device 234). Accordingly, the ReNAT twin NAT client 210 assigns data received from the user applications 208 UPIP. The ReNAT twin NAT client 210 may be configured to translate both source and destination IP addresses in the clear text packets to/from assigned UPIP. The COTS CTP client 212 receives and processes the data using clear text processing (or other protocol). The COTS VPN client 214 receives the data and creates a VPN tunnel for securely communicating the data to the NOC 204.

The NOC 204 receives the data at a COTS VPN 220 which removes the VPN encryption and provides the data for processing by the COTS clear text process manager 222. The COTS clear text process manager 222 processes the data according to clear text or other similar protocol. The data may then be processed by a ReNAT twin NAT 224. The ReNAT twin NAT 224 removes the UPIP and replaces the UPIP with

5

a customer-defined private IP from the private network **233** and provides the public IP address of the customer gateway device **232**. The ReNAT twin NAT **224** may be configured to translate both source and destination IP addresses in the clear text packets to/from assigned UPIP. For inbound packets, ReNAT twin NAT **224** uses the source IP provided by the ReNAT VPN **226** to identify the user. Outbound packets from the ReNAT twin NAT **224** to ReNAT VPN **226** include the destination public IP to identify the remote computing device **234**. For outbound packets, the ReNAT Twin NAT **224** uses the source and destination UPIP address to identify the destination public IP address for the destination Gateway/VPN **232**. Additionally, the VPN function is modified to provide the source IP on the external packets from the corporate office to identify the source gateway/VPN. Packets from ReNAT twin NAT **224** include the destination public IP to identify the destination Gateway/VPN.

Also included with the NOC **204** are a login manager **228** and a session manager **230**, which manage login of the user workstation **202** and managing the session of the user workstation. On the link between ReNAT twin NAT **224** and ReNAT VPN **226**, packets are wrapped in a private ReNAT-defined IP protocol that includes the public source and destination IP. Additionally, the ReNAT twin NAT **224** may assign a UPIP that overlaps with a customer assigned private IP address. However, this does not create routing issues since the assigned address is unique within the NOC and mapped to the public IP by session manager **230**. As discussed above, the session manager **230** maintains session information for each user workstation **202** that is logged into the service. The session manager **230** provides UPIP coordination information to the ReNAT twin NAT **224** and updates client session manager **218** with assigned UPIP for this customer. The session manager **230** also maintains the relationship between UPIP and public IP of the customer's Gateway/VPN. The corporate office **206** includes a customer gateway device **232**, a private network **233**, and the remote computing device **234**.

FIG. 3 depicts a computing environment to communicate with a remote computing device **308**, according to embodiments described herein. As illustrated, a customer may not have a VPN to the customer's corporate office but may desire to utilize a VPN between the NOC and their workstation. Regardless, the user workstation **302** of FIG. 3 includes user applications **310**, a COTS CTP client **312**, a COTS VPN client **314**, a client login manager **316**, and a client session manager **318**. As described above, the user applications **310** may communicate data to the COTS CTP client **312** for eventual communication via network **304** to the remote computing device **308**. The network **304** may include any wide area and/or local area network, such as the Internet.

Accordingly, the client login manager **316** and the client session manager **318** may communicate with the login manager **324** and the session manager **326** to facilitate logging into and managing a session with the NOC **306**. Once the session is established, the COTS CTP client **312** may process the data. Additionally, the COTS VPN client **314** may create a VPN tunnel between the user workstation **302** and the NOC **306** COTS VPN **320**. The user workstation **302** may receive the data and send the data to the NOC **306**. The NOC **306** can use the COTS VPN **320** to decrypt the data from the VPN and the COTS Clear Text Process **322** can further process the data for sending to the remote computing device **308**.

FIG. 4 depicts a computing environment for communicating with a remote computing device **408** without utilizing a VPN, according to embodiments described herein. Specifically, FIG. 4 depicts multiple COTS process so that the customer can choose a desired level of service. For example, one

6

COTS process may provide full acceleration of all traffic while a second COTS process only accelerates a portion of the traffic (such as all hypertext transfer protocol). Accordingly, the user workstation **402** of FIG. 4 may include user applications **410** for interacting with the remote computing device **408**. Accordingly, the client login manager **414** and the client session manager **416** may communicate with the login manager **420** and the session manager **422** for establishing a connection between the user workstation **402** and the NOC **406**. The user applications **410** may additionally generate data that the COTS CTP client **412** processes. The data is then sent using network **404**, which communicates the data to the NOC **406**. As described above, the network **404** may be any wide area or local area network. Depending on user settings, user selections, NOC settings, etc., the NOC **406** may implement one or more different COTS clear text processes **418** to process some or all of the data received. The NOC **406** may send the data to the remote computing device **408** for processing.

FIG. 5 depicts a flowchart that includes actions that a client workstation may perform for communicating with a remote computing device, according to embodiments described herein. As illustrated in block **550**, a license ID may be validated, such as via the login manager. In block **552**, the customer requesting the service may be identified. In block **554**, a session may be created to track the user. In block **556**, a VPN tunnel may be created for the user workstation and a UPIP address may be assigned to the license ID to the user workstation. In block **558**, a VPN tunnel may be created to the remote computing device. In block **560**, an emulation of the user logging into the remote computing device may be performed. In block **562**, customer VPN login data may be sent back to the user workstation to enter login credentials. In block **564**, the session manager may be updated with the login results. In block **566** the ReNAT twin NAT may be updated with the UPIP address for the remote computing device. In block **568**, a message indicating that the system is ready may be provided.

As described with reference to FIG. 5, the user workstation may initialize the session for communicating with the remote computing device. FIG. 6 depicts a flowchart that includes actions that a user workstation may perform in facilitating communication with a remote computing device once a session has been established, according to embodiments described herein. As illustrated in block **650**, the NOC may create a request datagram, based on user input. Specifically, this action may be created by the user workstation via the user application. Regardless, in block **652**, the user workstation may map customer defined private IP addresses in the datagram to UPIP addresses. In block **654**, the user workstation may process the datagram. In block **656**, the datagram may be transferred to the NOC.

It should be understood that in FIGS. 3 and 4, a network **304**, **404** is depicted between system components for illustrating utilization of the public Internet or other computing network. As will be understood, these are merely examples, as any of the components depicted in FIGS. 1-6 may be connected via a network infrastructure, depending on the embodiment.

FIG. 7 depicts a flowchart that includes actions that a NOC may perform in facilitating communication between a user workstation and a remote computing device, according to embodiments described herein. As illustrated in block **750**, the datagram may be processed by the NOC and a different datagram may be generated for sending to the remote computing device. In block **752**, UPIP addresses may be mapped

7

in the datagram to customer-defined private IP addresses. In block **754**, the datagram may be encrypted and transferred to the remote computing device.

FIG. **8** depicts another flowchart that includes actions that a NOC may perform in facilitating communication between a user workstation and a remote computing device, according to embodiments described herein. Specifically, while FIG. **7** depicts actions that may be performed when the user workstation sends data to the remote computing device, FIG. **8** depicts actions that may be performed when the remote computing device sends data to the user workstation. Accordingly, in block **850**, an encrypted response datagram with a destination IP address to a customer private IP for the user workstation may be received. In block **852**, the datagram may be decrypted. In block **854**, the customer-defined private IP addresses may be mapped in the datagram to UPIP addresses. In block **856**, a new customer private IP may be recorded from the source IP in the decrypted datagram and a new UPIP may be assigned. In block **858** the client session manager may be informed about the new UPIP to customer private IP mapping. In block **860**, the datagram may be processed and a new datagram may be generated for the user application. In block **862**, the new datagram may be sent to the user workstation.

It should be understood that, depending on the particular embodiment, one or more datagrams may be communicated to the remote computing device before generating the new datagram for the user workstation. As an example, if the computing environment is utilizing acceleration as the COTS process, the communication of multiple datagrams with the remote computing device may be performed.

FIG. **9** depicts a flowchart that includes actions that a user workstation may perform in receiving data from a remote computing device via a NOC, according to embodiments described herein. As illustrated in block **950**, the received datagram may be processed. In block **952**, UPIP addresses may be mapped in the datagram to customer-defined private IP addresses. In block **954**, the results in the datagram may be provided for display.

FIG. **10** depicts various hardware components that may be present in the NOC **204**, according to embodiments described herein. In the illustrated embodiment, the NOC **204** includes one or more processor **1030**, input/output hardware **1032**, network interface hardware **1034**, a data storage component **1036** (which stores login data **1038a** and session data **1038b**), and the memory component **1040**. The memory component **1040** may be configured as volatile and/or nonvolatile memory and, as such, may include random access memory (including SRAM, DRAM, and/or other types of RAM), flash memory, registers, compact discs (CD), digital versatile discs (DVD), and/or other types of non-transitory computer-readable mediums. Depending on the particular embodiment, the non-transitory computer-readable medium may reside within the NOC **204** and/or external to the NOC **204**.

Additionally, the memory component **1040** may be configured to store operating logic **1042**, the data communication logic **1044a**, and the manager logic **1044b**, each of which may be embodied as a computer program, firmware, and/or hardware, as an example. A local communications interface **1046** is also included in FIG. **10** and may be implemented as a bus or other interface to facilitate communication among the components of the NOC **204**.

The processor **1030** may include any processing component operable to receive and execute instructions (such as from the data storage component **1036** and/or memory component **1040**). The input/output hardware **1032** may include and/or be configured to interface with a monitor, keyboard, mouse, printer, camera, microphone, speaker, and/or other

8

device for receiving, sending, and/or presenting data. The network interface hardware **1034** may include and/or be configured for communicating with any wired or wireless networking hardware, a satellite, an antenna, a modem, LAN port, wireless fidelity (Wi-Fi) card, WiMax card, mobile communications hardware, fiber, and/or other hardware for communicating with other networks and/or devices. From this connection, communication may be facilitated between the NOC **204** and other computing devices.

Similarly, it should be understood that the data storage component **1036** may reside local to and/or remote from the NOC **204** and may be configured to store one or more pieces of data for access by the NOC **204** and/or other components. In some embodiments, the data storage component **1036** may be located remotely from the NOC **204** and thus accessible via a network connection. In some embodiments however, the data storage component **1036** may merely be a peripheral device, but external to the NOC **204**.

Included in the memory component **1040** are the operating logic **1042**, the data communication logic **1044a**, and the manager logic **1044b**. The operating logic **1042** may include an operating system and/or other software for managing components of the NOC **204**. Similarly, the data communication logic **1044a** may include the COTS VPN **220**, the COTS clear text process manager **222**, the ReNAT twin NAT **224**, the ReNAT VPN **226**, and/or other pieces of logic for manipulating data and communicating the data between a user workstation **202** and the remote computing device **234**. The manager logic **1044b** may include the login manager **228**, the session manager **230**, and/or other components that cause the NOC **204** to establish sessions with the user workstation **202**.

It should be understood that the components illustrated in FIG. **10** are merely exemplary and are not intended to limit the scope of this disclosure. While the components in FIG. **10** are illustrated as residing within the NOC **204**, this is merely an example. In some embodiments, one or more of the components may reside external to the NOC **204**. It should also be understood while the NOC **204** is depicted in FIG. **10**, other computing devices described in FIG. **2** or other drawings may include similar hardware and software for providing the described functionality.

While particular embodiments have been illustrated and described herein, it should be understood that various other changes and modifications may be made without departing from the spirit and scope of the claimed subject matter. Moreover, although various aspects of the claimed subject matter have been described herein, such aspects need not be utilized in combination. It is therefore intended that the appended claims cover all such changes and modifications that are within the scope of the claimed subject matter.

What is claimed is:

1. A system for providing redundant network address translation (ReNAT) communications, comprising a network operations center (NOC), the NOC comprising:

a computing device that stores logic, including at least the following:

a first virtual private network (VPN) component that initiates a VPN communication with a private network;

a ReNAT twin network address translation (NAT) that is coupled to the first VPN component, wherein the ReNAT twin NAT translates between a customer-assigned private IP address and a unique private IP (UPIP) address, wherein the UPIP overlaps with the customer-assigned private IP address and wherein the UPIP is unique within the NOC;

a ReNAT VPN component coupled to the ReNAT twin NAT, wherein the ReNAT VPN component provides a source IP address to the ReNat twin NAT; and communication logic that causes the system to facilitate communication with a user workstation that includes a VPN client and a ReNAT twin NAT client, wherein, in communicating the data with the private network, the NOC receives data via a VPN portal, wherein address translation has been performed by the ReNAT twin NAT client;

wherein the ReNAT twin NAT maps addresses in the data to customer defined private addresses and wherein the ReNAT VPN encrypts the data and transfers the data to the private network.

2. The system of claim 1, further comprising the private network, which includes a remote computing device, and a gateway device.

3. The system of claim 1, wherein the logic further includes a login manager that causes the system to provide a user login option for logging onto the private network.

4. The system of claim 1, wherein the logic further includes a clear text component that manages IP addresses of a plurality of computing devices within a plurality of user organizations and ensures each of the plurality of computing devices has a unique IP address.

5. The system of claim 1, further comprising a session manager that provides data for identifying a remote computing device with which to communicate.

6. The system of claim 1, wherein the ReNAT twin NAT client and the ReNAT twin NAT are coordinated to translate between customer-assigned private IP addresses and ReNAT assigned UPIP so that the user workstation and the private network see only respective internal private IP addresses.

7. The system of claim 1, wherein ReNAT twin NAT assigns a unique private IP address (UPIP) for each computing device.

8. A network operations center (NOC) comprising:
a computing device that stores logic, including at least the following:
a ReNAT twin network address translation (NAT) that translates between a customer-assigned private IP address and a unique private IP (UPIP) address, wherein the UPIP overlaps with the customer-assigned private IP address and wherein the UPIP is unique within the NOC;
a redundant network address translation (ReNAT) virtual private network (VPN) component coupled to the ReNAT twin NAT, wherein the ReNAT VPN provides a source IP address to the ReNat twin NAT; and communication logic that causes the NOC to facilitate communication between a user workstation on a private network and a remote computing device, wherein facilitating communication includes receiving the data from the user workstation via a VPN portal, wherein address translation has been performed by a ReNAT twin NAT client on the user workstation;
wherein the ReNAT twin NAT maps addresses in the data to customer defined private addresses and wherein the ReNAT VPN encrypts the data and transfers the data to the private network.

9. The NOC of claim 8, further comprising the private network, which includes the remote computing device, and a gateway device.

10. The NOC of claim 8, wherein the logic further includes a login manager that causes the processor to provide a user login option for logging onto the private network.

11. The NOC of claim 8, wherein the logic further includes a clear text component that manages IP addresses of a plurality of computing devices within a plurality of user organizations and ensures each of the plurality of computing devices has a unique IP address.

12. The NOC of claim 8, further comprising a session manager that provides data for identifying a remote computing device with which to communicate.

13. The NOC of claim 8, wherein the ReNAT twin NAT client and the ReNAT twin NAT are coordinated to translate between customer-assigned private IP addresses and ReNAT assigned UPIP so that the user workstation and the private network see only respective internal private IP addresses.

14. The NOC of claim 8, wherein ReNAT twin NAT assigns a unique private IP address (UPIP) for each computing device.

15. A non-transitory computer-readable medium that stores logic that, when executed by a computing device, causes the computing device to perform at least the following:
initiate a virtual private network (VPN) communication with a private network;
translate between a customer-assigned private IP address and a unique private IP (UPIP) address, wherein the UPIP overlaps with the customer-assigned private IP address and wherein the UPIP is unique within the NOC;
provide a source IP address to a redundant network address translation (ReNAT) twin network address translation (NAT); and
facilitate communication with a user workstation wherein, communicating the data includes receiving data via a VPN portal, wherein address translation has been performed by a ReNAT twin NAT client on the user workstation;
map addresses in the data to customer defined private addresses and
encrypt the data and transfers the data to the private network.

16. The non-transitory computer-readable medium of claim 15, further comprising the private network, which includes a remote computing device, and a gateway device.

17. The non-transitory computer-readable medium of claim 15, further comprising a login manager that causes the computing device to provide a user login option for logging onto the private network.

18. The non-transitory computer-readable medium of claim 15, further comprising a clear text component that manages IP addresses of a plurality of computing devices within a plurality of user organizations and ensures each of the plurality of computing devices has a unique IP address.

19. The non-transitory computer-readable medium of claim 15, further comprising a session manager that provides data for identifying a remote computing device with which to communicate.

20. The non-transitory computer-readable medium of claim 15, wherein the ReNAT twin NAT client and the ReNAT twin NAT are coordinated to translate between customer-assigned private IP addresses and ReNAT assigned UPIP so that the user workstation and the private network see only respective internal private IP addresses.

21. A method for providing redundant network address translation (ReNAT) communications, comprising:
initiating a virtual private connection with a private network;
translating between a customer-assigned private internet protocol (IP) address and a unique private IP (UPIP) address, wherein the UPIP overlaps with the customer-

11

assigned private IP address and wherein the UPIP is
unique within a network operations center (NOC) in
which the UPIP is utilized;
facilitating communication between a user workstation
that includes a ReNAT twin NAT client and the private 5
network, wherein address translation has been per-
formed by the ReNAT twin NAT client;
mapping addresses in the data to customer-defined IP
addresses; and
encrypting the data and transferring the data to the private 10
network.

22. The method of claim **21**, further comprising translating
between the customer-assigned private IP addresses and
ReNAT assigned UPIP so that the user workstation and the
private network see only respective internal private IP 15
addresses.
